### 1. AUGUST 23, 2022

This class is, as its name makes clear, is all about differential equations. Let's start with an example that is probably similar to something you've seen in Calculus.

**Example 1.1.** The equation

$$\frac{dy}{dx} = 7y$$

is a differential equation. The unknown in this equation,  $y$ , stands for a function. What makes this equation a differential equation is that the equation relates the mystery function and its derivative.

Let's see if we can guess a solution. This equation might remind us of a curious calculus coincidence. If the 7 wasn't there, we would be looking for a function whose derivative is equal to itself;  $e^x$  would work.

Let's try  $y = 7e^x$  for our original equation. To test it, we plug it in:

$$y = 7e^x \rightsquigarrow y' = (7e^x)' = 7e^x \neq 7y = 49e^x.$$

How about putting the 7 somewhere else:

$$y = e^{7x} \rightsquigarrow y' = (e^{7x})' = e^{7x}(7x)' = 7e^{7x} = 7y.$$

So  $e^{7x}$  is a solution!

Could there be any others?

$$y = 5e^{7x} \rightsquigarrow y' = (5e^{7x})' = 5e^{7x}(7x)' = 7(5e^{7x}) = 7y.$$

In general,  $y(x) = Ce^{7x}$  is a solution for any constant  $C$ .

Of course, at the end of the day, nothing was special about 7. If we replaced 7 by any real number  $a$ , for the same reason, we would find that for the differential equation

$$y' = ay$$

the *general solution* is

$$y(x) = Ce^{ax}.$$

Guessing, while successful here, is not going to be our preferred method in the class. Let's savor this victory, and be prepared to collect many methods for solving differential equations as we progress through the course.

**Types of differential equations.** There are many different ways of throwing together functions and derivatives in an equation, so we'll need some terminology to orient ourselves.

**Definition 1.2.** An *ordinary differential equation (ODE)* is a differential equation involving only one independent variable; i.e., derivatives with respect to just one variable.

For example,

$$\frac{d^2y}{dt^2} + t\frac{dy}{dt} = -y + \cos(ty)$$

is an ordinary differential equation.

In general an ODE is an equation of the form

$$F(t, y, y', y'', \dots, y^{(n)}) = 0$$

for some function  $F$  where  $y = y(t)$ : an equation relating the function  $y$  with its derivative(s).

**Definition 1.3.** A *partial differential equation (PDE)* is a differential equation involving multiple independent variable; i.e., derivatives with respect to different variables.

For example,

$$\frac{\partial u}{\partial t} - 5\frac{\partial u}{\partial x} = 0$$

and

$$\frac{\partial^2 z}{\partial x \partial y} - z^2 = xy$$

are PDEs. A solution of the first PDE would be a function  $u(x, t)$  that depends two independent variables  $x$  and  $t$ .

The “ordinary” vs “partial” refers to what type of derivatives see.

This is a class about ODEs. Almost all of the rest of the differential equations we see this semester will be ordinary!

**Definition 1.4.** The *order* of a differential equation is the highest order derivative that occurs in the equation.

For example,

$$yy'' + y''' + \frac{1}{y} = 5x$$

is a third order ODE, due to the  $y'''$  term and

$$\frac{d^2y}{dt^2} + t\frac{dy}{dt} = -y + \cos(ty)$$

is a second order ODE.

**Definition 1.5.** A *linear* ODE is any ODE of the form

$$a_n(t)y^{(n)} + a_{n-1}(t)y^{(n-1)} + \cdots + a_2(t)y'' + a_1(t)y' + a_0(t)y = f(t).$$

For example,

$$5ty'' + \ln(t)y' + y = \cos(t)$$

is a second order linear ODE, but

$$yy' + 5y = 7$$

and

$$(y')^3 - ty^2 = 3e^t$$

are first order nonlinear ODEs.

We will be especially interested in linear ODEs in this course!

### Discussion Questions.

- (1) Is the differential equation  $y' = y^{2/3}$  ordinary? linear? What is its order?

Ordinary yes, linear no, order 1.

- (2) Which of the following is a solution to the differential equation  $y' = y^{2/3}$ :

- (a)  $y = 8t^2$
- (b)  $y = e^{2t/3}$
- (c)  $y = \frac{1}{27}t^3$
- (d)  $y = 0$  (constant function 0)

- (a) No:  $y' = 16t \neq y^{2/3} = 4t^{4/3}$ .
- (b) No:  $y' = 2/3 e^{2t/3} \neq y^{2/3} = (e^{2t/3})^{2/3} = e^{4t/9}$ .
- (c) Yes:  $y' = \frac{1}{9}t^2 = y^{2/3}$ .
- (d) Yes:  $y' = 0 = y^{2/3}$ .

- (3) There is a solution to  $xy'' = (4x - 4)y$  of the form  $y = xe^{ax}$  for some real number  $a$ . Find  $a$ .

By the product rule,  $y' = (ax + 1)e^{ax}$  and  $y'' = (a^2x + 2a)e^{ax}$ , so  $xy'' - (4x - 4)y = (a^2x^2 + 2ax)e^{ax} - (4x - 4)xe^{ax}$ . We must have  $a^2x^2 + 2ax = 4x^2 - 4x$ , so  $a = -2$ .

- (4\*) If  $f, g$  are solutions to  $y^{(3)} + 2e^xy^{(2)} - y = \cos(x)$ , show that  $\frac{f+g}{2}$  is too.

**Initial value problems; existence and uniqueness.** In our first example, we saw that there are many solutions to the differential equation  $y' = 7y$ . To pin one down, we might specify a value for our function at a point. The system

$$\begin{cases} y' = 7y \\ y(2) = 4 \end{cases}$$

is an example of an *initial value problem*. Geometrically,  $y(2) = 4$  corresponds to the condition that the graph of our solution passes through  $(2, 4)$ .

We can solve this using our solution of  $y' = 7y$  from earlier. We have

$$y = Ce^{7x} \quad y(2) = 4$$

so

$$4 = Ce^{7 \cdot 2}$$

and

$$C = 4e^{-14}.$$

That is,

$$y = 4e^{-14}e^{7x} = 4e^{7x-14}.$$

Not only did we find a solution to our IVP, but along the way we saw that our solution was the only one; i.e., is unique (as long as we believe we started off with all of the solutions to  $y' = 7y$ ).

On the other hand, we have the following.

**Example 1.6.** Consider the IVP

$$\begin{cases} y' = y^{2/3} \\ y(0) = 0 \end{cases}.$$

We saw in the discussions questions that  $y = 0$  and  $y = \frac{1}{27}t^3$  both satisfy the first differential equation and it's easy to see they also satisfy the initial condition, so they are also both solutions to the IVP so here we have an IVP for which the solution is not unique.

What if we are so unlucky as to try to solve an IVP and there's no solution at all?

**Theorem 1.7** (Picard-Lindelöf). *For the IVP*

$$\begin{cases} \frac{dy}{dx} = f(x, y) \\ y(x_0) = y_0 \end{cases}$$

*and some rectangle  $R$  in the  $(x, y)$ -plane containing  $(x_0, y_0)$  in its interior, there exists a unique solution on some possibly smaller interval  $(x_0 - h, x_0 + h)$ , so long as  $f$  and  $\frac{\partial f}{\partial y}$  are continuous on  $R$ .*

**Example 1.8.** Consider the differential equation

$$\frac{dy}{dx} = 5xy.$$

We want to use the Picard-Lindelöf Theorem to show that for any initial condition  $y(x_0) = y_0$ , there is a unique solution near  $x_0$ . The  $f(x, y)$  of the Theorem is  $5xy$ ; this is continuous on all of  $\mathbb{R}^2$ . We also need to look at  $\frac{\partial f}{\partial y} = 5x$ . This is also continuous on all of  $\mathbb{R}^2$ . We conclude that

$$\begin{cases} \frac{dy}{dx} = 5xy \\ y(x_0) = y_0 \end{cases}$$

has a unique solution, no matter what  $x_0$  and  $y_0$  are.

**Example 1.9.** Let's consider

$$\begin{cases} y' = y^{2/3} \\ y(x_0) = y_0 \end{cases}.$$

Here  $f(x, y) = y^{2/3}$  and  $\frac{\partial f}{\partial y}(x, y) = \frac{2}{3}y^{-1/3}$ .  $f$  is continuous everywhere, but  $f'$  is only continuous where  $y_0 \neq 0$ . Thus, if  $y_0 \neq 0$ , then there is a unique solution.

However, if  $y_0 = 0$ , the theorem does not apply. We looked at this example earlier and saw that the solutions were not unique for  $(x_0, y_0) = (0, 0)$ .

**Example 1.10.** Let's consider

$$\begin{cases} y' = \frac{y^2}{t^2-4} \\ y(-1) = 3 \end{cases}.$$

What is the largest interval on which the Picard-Lindelöf Theorem guarantees the existence of a unique solution? We have, in the notation of the Theorem,

$$f = \frac{y^2}{t^2-4} \quad \frac{\partial f}{\partial y} = \frac{2y}{t^2-4}.$$

These are continuous except when  $t = \pm 2$ . Thus, any rectangle whose base is contained in  $(-2, 2)$  will satisfy the hypotheses of the theorem, so  $(-2, 2)$  is the interval we seek.

## 2. AUGUST 25, 2022

**Modeling with differential equations.** Differential equations is one of the most useful areas of math for applications, since so many real life things are described effectively by differential equations. A *mathematical model* is a description of some system or phenomenon by an

equation or a formula. A model is rarely perfect, since we can't even know all of the factors that might affect something, but we can often use them to understand things better.

Let's start with a basic example.

**Example 2.1.** A classical model of human population growth is based on the assumption that the rate at which the population of a country grows is proportional to the population of that country. To express this as a differential equation, let  $P$  the population of a country. We are interested in how it changes, so let  $t$  be a variable for time and view  $P$  as a function of  $t$ . To say that two things are proportional means that there exists a constant  $k$  (called the *constant of proportionality*) such that  $k$  times the first quantity is the second quantity. The rate of change of the population is  $\frac{dP}{dt}$ . Thus, our equation is

$$\frac{dP}{dt} = kP$$

for some constant  $k$ . We do not know what  $k$  is without further information.

This is the only differential equation we've solved! We must have

$$P(t) = Ce^{kt}.$$

Given two data points for any specific population, we can determine  $C$  and  $k$ .

Let us try to set up a more complicated model.

**Example 2.2.** Say that we have a tank of water. At first, it holds 500 liters of pure water (no salt). After switch is flipped, salt water that has 7 grams of salt per liter starts flowing in at a rate of 2 liters per minute, and water from the bottom of the tank starts flowing out at a rate of 2 liters per minute. Let's model the amount of salt in the tank at a given time after the switch is flipped.

Let  $A$  be the amount of salt in the tank, in grams, and  $t$  be the amount of time since the switch is flipped in minutes. We need to understand the rate of change of  $A$ . Salt enters at a rate of  $7 \cdot 2 = 14$  grams per minute. To find the rate at which salt exits, the amount of salt in an average liter of water is  $A/500$  grams per liter, so the amount of salt exiting is  $2 \cdot A/500 = A/250$ .

We obtain the differential equation

$$\frac{dA}{dt} = 14 - \frac{A}{250}.$$

We also have the initial condition  $A(0) = 0$ .

We will learn how to solve systems like this soon.

**Discussion Questions.** The government of a country wants to remove counterfeit money from circulation. Say there are 20 million total bills in circulation. Every day, 3 million of its bills pass through federal banks, and every counterfeit bill collected is replaced by a legal one. Say that half of the total bills in circulation today are counterfeit. Let's assume that the total number of bills in circulation stays constant and that no more counterfeit bills are being introduced. Our goal is to find an initial value problem modeling the percentage of counterfeit bills in circulation as time passes.

- (1) Introduce variables to keep track of the quantities we are interested in. What is the independent variable and what is the dependent variable? What are the units for each?
- (2) To set up a differential equation, we want to relate the dependent variable with its rate of change. How much does the percentage of counterfeit bills change in a given day, on average?
- (3) We also need an initial condition. Write it down.
- (4) This is a type of differential equation we've solved already. Find an explicit solution.
- (5) Based on your model, when will the total number of counterfeit bills pass below 3 million?

Let's do an experiment to test our model. Each coin you've been given represents a million bills. Some represent valid coins and some represent counterfeits. Every day, take two random coins; replace the counterfeits with legal ones, and leave the legal ones alone.

- (1) Discuss whether your model for the previous situation is relevant to this experiment. What aspects fit the story well, and what ones don't?
- (2) Run the experiment, keeping track of the number of counterfeit bills each day, and how long it takes to get down to 2 counterfeits.

Now let's change our original story. As before, every day, 2 million of its bills pass through federal banks, and every counterfeit bill collected is replaced by a legal one. Say that half of the 20 million total bills in circulation today are counterfeit. But now, let's assume that 1 million new legal bills and 1 million new counterfeit bills are put into circulation each day.

- (1) Create a new differential equation and initial value problem to model this situation.
- (2) This is not a differential equation that we have solved yet. We will learn how to find explicit solutions of equations like this soon! But even without knowing what exactly the solution is,

explain why there is one and only one solution to this initial value problem.

- (3) Run an experiment similar to the one above adapted to this situation.
- (4) Based on the experiment, what do we expect to happen to the currency as time passes?
