

REMINDER ON FUNCTIONS

Given any two sets S and T , a *function* from S to T , written $f : S \rightarrow T$, is a “rule”¹ that assigns to each element $s \in S$ a unique element $t \in T$. The set S is called the *domain* of f . We will generally consider functions from some set of real numbers to \mathbb{R} . We often specify functions by formulas; when we do this we take the domain to be the set of all real numbers for which the formula evaluates to a unique real number. In particular,

$$f(x) = 2x + 2 \quad \text{and} \quad g(x) = \frac{2x^2 - 2}{x - 1}$$

are *not* the same function, even though their values agree for all $x \neq 1$, since their domains are different.

LIMITS OF FUNCTIONS

Definition 17.1: Let S be a subset of \mathbb{R} . Let $f : S \rightarrow \mathbb{R}$ be a function, and a and L be real numbers. We say that *the limit of f as x approaches a is L* provided:

for any $\varepsilon > 0$ there exists $\delta > 0$ such that if $0 < |x - a| < \delta$, then x is in the domain of f and $|f(x) - L| < \varepsilon$.

If this happens, we write $\lim_{x \rightarrow a} f(x) = L$ to denote this.

(1) UNPACKAGING PARTS OF THE DEFINITION.

- (a) Describe $\{x \in \mathbb{R} \mid 0 < |x - 2| < 1\}$ as a union of two open intervals.
- (b) For a general $a \in \mathbb{R}$ and $\delta > 0$, describe $\{x \in \mathbb{R} \mid 0 < |x - a| < \delta\}$ as a union of two open intervals.
- (c) Focusing on the “domain” part of the definition, if the limit of f as x approaches a is L , then f must at least be defined _____ (where?).

(2) THE $\varepsilon - \delta$ GAME.

- (a) Player 0 starts by graphing a function f (like a familiar one from calculus) and specifies an x -value a and a y -value L that (based on previous calculus knowledge) they think makes $\lim_{x \rightarrow a} f(x) = L$ **true**. [The graph should be large.]
- (b) Player 1 chooses an ε . This is how close we would like our function to be to L . Thus, ε goes up and down from L (corresponding to $|f(x) - L| < \varepsilon$). Draw horizontal dotted lines with y -values $L - \varepsilon$ and $L + \varepsilon$. [The ε should be large enough for people to see and have room to work in the picture.]
- (c) Player 2 must find a δ such that every $x \in (a - \delta, a) \cup (a, a + \delta)$ is
 - in the domain of f , and
 - has an output $f(x)$ within $(L - \varepsilon, L + \varepsilon)$.
 Draw vertical dotted lines for the x -values $a - \delta$ and $a + \delta$. [Everyone in the team can assist player 2!]
- (d) Repeat with the same graph, players 1 & 2 switching roles (and a new ε).

- (3) Draw the graph of $g(x) = \frac{2x^2 - 2}{x - 1}$. Play the $\varepsilon - \delta$ game with this function, $a = 1$ and $L = -3$. What happens?

¹Here’s a real definition: a *function* from S to T is a subset $G \subset S \times T$ of ordered pairs of elements of S and T with the property that for all $s \in S$ there is a unique $t \in T$ such that $(s, t) \in G$; we write $f(s)$ for this element t .

- (4) Consider the function $g(x) = \frac{2x^2 - 2}{x - 1}$. It is true that $\lim_{x \rightarrow 1} g(x) = 4$.
- (a) I claim that for $\varepsilon = 3$, the choice $\delta = 3$ “works” to make the rest of the definition true. Verify this.
 - (b) Find a δ that “works” for $\varepsilon = 1$.
 - (c) Find a δ that “works” for $\varepsilon = 1/2$.
 - (d) Find a δ that “works” for $\varepsilon > 0$.
- (5) Consider the function $g(x) = \frac{2x^2 - 2}{x - 1}$. It is not true that $\lim_{x \rightarrow 1} g(x) = -3$. I claim that for $\varepsilon = 1$, there is no choice of $\delta > 0$ that “works” to make the rest of the definition true. Verify this.
- (6) Repackage your work from (4) to *prove* that $\lim_{x \rightarrow 1} g(x) = 4$.
- (7) Repackage your work from (5) to *disprove* that $\lim_{x \rightarrow 1} g(x) = -3$.
(Warning: Until we prove something else, the conclusion of (6) is irrelevant to this problem. . . prove what?)
