Lecture of January 19, 2022

In this class, all rings are assumed to be commutative, with associative multiplication and containing 1.

1. Finiteness conditions

1.1. **Finitely generated algebras.** We start by recalling a definition from last semester, specialized to the setting of commutative rings.

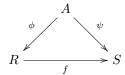

Definition 1.1 (Algebra). Given a ring A, an A-algebra is a ring R equipped with a ring homomorphism $\phi: A \to R$. This defines an A-module structure on R given by restriction of scalars, that is, for $a \in A$ and $r \in R$, $ar := \phi(a)r$ that is compatible with the internal multiplication of R i.e.,

$$a(rs) = (ar)s = r(as)$$
 for all $a \in A, rs \in R$.

We will call ϕ the structure homomorphism of the A-algebra R.

- **Example 1.2.** If A is a ring and x_1, \ldots, x_n are indeterminates, the inclusion map $A \hookrightarrow A[x_1, \ldots, x_n]$ makes the polynomial ring into an A-algebra.
 - When $A \subseteq R$ the inclusion map makes R an A-algebra. In this case the A-module multiplication ar coincides with the internal (ring) multiplication on R.
 - Any ring comes with a unique structure as a Z-algebra.

The collection of A-algebras forms a category where the morphisms are ring homomorphisms $f: R \to S$ such that the following diagram commutes

for structural homomorphisms $\varphi: A \to R$ and $\psi: A \to S$.

Definition 1.3 (Algebra generation). Let R be an A-algebra and let $\Lambda \subseteq R$ be a set. The A-algebra generated by a subset Λ of R, denoted $A[\Lambda]$, is the smallest (w.r.t containment) subring of R containing Λ and $\varphi(A)$.

A set of elements $\Lambda \subseteq R$ generates R as an A-algebra if $R = A[\Lambda]$.

Note that there are two different meanings for the notation A[S] for a ring A and set S: one calls for a polynomial ring, and the other calls for a subring of something.

This can be unpackaged more concretely in a number of equivalent ways:

Lemma 1.4. The following are equivalent

- (1) Λ generates R as an A-algebra.
- (2) Every element in R admits a polynomial expression in Λ with coefficients in $\phi(A)$, i.e.

$$R = \left\{ \sum_{\text{finite}} \phi(a) \lambda_1^{i_1} \cdots \lambda_n^{i_n} \mid a \in A, \lambda_j \in \Lambda, i_j \in \mathbb{N} \right\}.$$

(3) The A-algebra homomorphism $\psi : A[X] \to R$, where A[X] is a polynomial ring on a set of indeterminates X in bijection with Λ and $\psi(x_i) = \lambda_i$, is surjective.

Proof. Let $S = \{\sum_{\text{finite}} \phi(a) \lambda_1^{i_1} \cdots \lambda_n^{i_n} \mid a \in A, \lambda_j \in \Lambda, i_j \in \mathbb{N} \}$. For the equivalence between (2) and (3) we note that S is the image of ψ . In particular, S is a subring of R. It then follows from the definition that (1) implies (2). Conversely, any subring of R containing $\phi(A)$ and Λ certainly must contain S, so (2) implies (1).

Example 1.5. We may have also seen these brackets used in $\mathbb{Z}[\sqrt{d}]$ for some $d \in \mathbb{Z}$ to describe the ring

$${a + b\sqrt{d} \mid a, b \in \mathbb{Z}}.$$

In fact, this is a special instance of generating: the \mathbb{Z} -algebra generated by \sqrt{d} in the most natural place, the algebraic closure of \mathbb{Q} , is exactly the set above. The point is that for any power $(\sqrt{2})^n$, write n = 2q + r with $r \in \{0, 1\}$, so $(\sqrt{2})^n = 2^d(\sqrt{2})^r$. Similarly, the ring $\mathbb{Z}[\sqrt[3]{d}]$ can be written as

$$\{a+b\sqrt[3]{d}+c\sqrt[3]{d^2}\mid a,b,c\in\mathbb{Z}\}.$$

Note that the homomorphism ψ in part (3) need not be injective.

- If the homomorphism ψ is injective (so an isomorphism) we say that A is a *free* algebra.
- the set $\ker(\psi)$ measures how far R is from being a free A-algebra and is called the set of *relations* on Λ .

Definition 1.6 (Algebra-finite). We say that $\varphi: A \to R$ is algebra-finite, or R is a finitely generated A-algebra, if there exists a finite set of elements f_1, \ldots, f_d that generates R as an A-algebra. We write $R = A[f_1, \ldots, f_d]$ to denote this.

The term *finite-type* is also used to mean this.

Remark 1.7. Note that, by the lemma on generating sets, an A-algebra is finitely generated if and only if it is isomorphic to a quotient of a polynomial ring over A in finitely many variables. The choice of an isomorphism with a quotient of a polynomial ring is equivalent to a choice of generating set.

Lecture of January 21, 2022

Example 1.8. Let K be a field, and $B = K[x, xy, xy^2, xy^3, \dots] \subseteq C = K[x, y]$, where x and y are indeterminates. Let A be a finitely generated subalgebra of B, and write $A = K[f_1, \dots, f_d]$. Since each f_i is a (finite) polynomial expression in the monomials $\{xy^i \mid i \in \mathbb{N}\}$, it involves only finitely many of these monomials. Thus, there is an m such that $\{f_1, \dots, f_d\} \subset K[x, xy, \dots, xy^m]$, and hence $A \subseteq K[x, xy, \dots, xy^m]$.

But, every element of $K[x, xy, ..., xy^m]$ is a K-linear combination of monomials with the property that the y exponent is no more than m times the x exponent, so this ring does not contain xy^{m+1} . Thus, B is not a finitely generated K-algebra.

Optional Exercise 1.9. Let $A \xrightarrow{\phi} B \xrightarrow{\psi} C$ be ring homomorphisms (so B is an A-algebra via ϕ , C is a B-algebra via ψ , and C is an A-algebra via $\psi \circ \phi$). Then

- If $A \xrightarrow{\phi} B$ and $B \xrightarrow{\psi} C$ are algebra-finite, then $A \xrightarrow{\psi\phi} C$ is algebra-finite. (Take the union of the generating sets.)
- If $A \xrightarrow{\psi \phi} C$ is algebra-finite, then $B \xrightarrow{\psi} C$ is algebra-finite. (Use the same generating set.)
- If $A \xrightarrow{\psi \phi} C$ is algebra-finite, then $A \xrightarrow{\phi} B$ may not be algebra-finite. (Use the previous example.)

Remark 1.10. Any surjective φ is algebra-finite: the target is generated by 1. Since any homomorphism $\phi:A\to R$ can be factored as $\phi=\psi\circ\varphi$ where φ is the surjection $\varphi:A\to A/\ker(\varphi)$ and ψ is the inclusion $\psi:A/\ker(\varphi)\hookrightarrow R$, to understand algebra-finiteness, it suffices to restrict our attention to injective homomorphisms by the last bullet point of the previous exercise.

There are many basic questions about algebra generators that are surprisingly difficult. Let $R = \mathbb{C}[x_1, \ldots, x_n]$ and $f_1, \ldots, f_n \in R$. When do f_1, \ldots, f_n generate R over \mathbb{C} ? It is not too hard to show that the Jacobian determinant

$$\det \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1} & \cdots & \frac{\partial f_n}{\partial x_n} \end{bmatrix}$$

must be a nonzero constant. It is a big open question whether this is in fact a sufficient condition!

1.2. **Finitely generated modules.** We will also find it quite useful to consider a stronger finiteness property for maps.

Definition 1.11. (Module generation) Let M be an A-module and let $\Gamma \subseteq M$ be a set. The A-submodule of M generated by Γ , denoted $\sum_{\gamma \in \Gamma} A\gamma$, is the smallest (w.r.t containment) submodule of M containing Γ .

A set of elements $\Gamma \subseteq M$ generates M as an A-module if the submodule of M generated by Γ is M itself, i.e. $M = \sum_{\gamma \in \Gamma} A\gamma$.

This also has some equivalent realizations:

Lemma 1.12. The following are equivalent:

- (1) Γ generates M as an A-module.
- (2) Every element of M admits a linear combination expression in the elements of Γ with coefficients in A.
- (3) The homomorphism $\theta: A^{\oplus Y} \to M$, where $A^{\oplus Y}$ is a free A-module with basis Y in bijection with Γ via $\theta(y_i) = \gamma_i$, is surjective.

Optional Exercise 1.13. Prove the previous lemma.

Definition 1.14 (Module-finite). We say that a ring homomorphism $\varphi: A \to R$ is module-finite if R is a finitely-generated A-module, that is, there is a finite set $m_1, \ldots, m_n \in M$ so that $M = \sum_{i=1}^n Am_i$.

As with algebra-finiteness, surjective maps are always module-finite in a trivial way. The notion of module-finite is much stronger than algebra-finite, since a linear combination is a very special type of polynomial expression. To be specific:

Lemma 1.15 (Module-finite \Rightarrow algebra-finite). If $\varphi: A \to R$ is module-finite then it is algebra-finite.

The converse is not true.

Example 1.16. (1) If $K \subseteq L$ are fields, L is module-finite over K just means that L is a finite field extension of K.

- (2) The Gaussian integers $\mathbb{Z}[i]$ satisfy the well-known property (or definition, depending on your source) that any element $z \in \mathbb{Z}[i]$ admits a unique expression z = a + bi with $a, b \in \mathbb{Z}$. That is, $\mathbb{Z}[i]$ is generated as a \mathbb{Z} -module by $\{1, i\}$; moreover, they form a free module basis!
- (3) If R is a ring and x an indeterminate, $R \subseteq R[x]$ is not module-finite. Indeed, R[x] is a free R-module on the basis $\{1, x, x^2, x^3, \dots\}$. It is however algebra-finite.
- (4) Another map that is *not* module-finite is the inclusion of $K[x] \subseteq K[x, 1/x]$. Note that any element of K[x, 1/x] can be written in the form $f(x)/x^n$ for some $f(x) \in K[x]$ and $n \in \mathbb{N}$. Then, any finitely generated K[x]-submodule M of K[x, 1/x] is of the form $M = \sum_i \frac{f_i(x)}{x^{n_i}} \cdot K[x]$; taking $N = \max\{n_i \mid i\}$, we find that $M \subseteq 1/x^N \cdot K[x] \neq K[x, 1/x]$.

Optional Exercise 1.17. Let $A \xrightarrow{\phi} B \xrightarrow{\psi} C$ be ring homomorphisms. Then

- If $A \xrightarrow{\phi} B$ and $B \xrightarrow{\psi} C$ are module-finite, then $A \xrightarrow{\psi \phi} C$ is module-finite.
- If $A \xrightarrow{\psi \phi} C$ is module-finite, then $B \xrightarrow{\psi} C$ is module-finite.

We will see that $A \xrightarrow{\psi \phi} C$ is module-finite does not imply $A \xrightarrow{\phi} B$ is module-finite soon.

1.3. **Integral extensions.** In field theory, there is a close relationship between (vector space-)finite field extensions and algebraic equations. The situation for rings is similar.

Definition 1.18 (Integral element/extension). Let $\phi: A \to R$ be a ring homomorphism (for which we will denote $\phi(a)$ by a) and $r \in R$. The element r is *integral* if there are elements $a_0, \ldots, a_{n-1} \in A$ such that

$$r^{n} + a_{n-1}r^{n-1} + \dots + a_{1}r + a_{0} = 0;$$

i.e., r satisfies a equation of integral dependence over A. The homomorphism ϕ is integral if every element of R is integral over A.

Example 1.19. Let $A = \mathbb{Z}[\sqrt{2}] = \{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$. The element $t = \sqrt{2} \in A$ is integral over \mathbb{Z} , since $t^2 - 2 = 0$. Likewise, $s = 1 + \sqrt{2}$ is integral over \mathbb{Z} , as $s^2 = 3 + 2\sqrt{2}$, so $s^2 - 2s - 1 = 0$.

On the other hand, $\frac{1}{2} \in \mathbb{Q}$ is not integral over \mathbb{Z} : if

$$\left(\frac{1}{2}\right)^n + a_{n-1} \left(\frac{1}{2}\right)^{n-1} + \dots + a_0 = 0$$

with $a_i \in \mathbb{Z}$, multiply through by 2^n to get $1 + 2a_{n-1} + 2^2a_{n-2} + \cdots + 2^na_0 = 0$, which is impossible.
