Lecture of January 19, 2022

In this class, all rings are assumed to be commutative, with associative multiplication and containing 1.

1. Finiteness conditions

1.1. **Finitely generated algebras.** We start by recalling a definition from last semester, specialized to the setting of commutative rings.

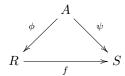

Definition 1.1 (Algebra). Given a ring A, an A-algebra is a ring R equipped with a ring homomorphism $\phi: A \to R$. This defines an A-module structure on R given by restriction of scalars, that is, for $a \in A$ and $r \in R$, $ar := \phi(a)r$ that is compatible with the internal multiplication of R i.e.,

$$a(rs) = (ar)s = r(as)$$
 for all $a \in A, rs \in R$.

We will call ϕ the structure homomorphism of the A-algebra R.

- **Example 1.2.** If A is a ring and x_1, \ldots, x_n are indeterminates, the inclusion map $A \hookrightarrow A[x_1, \ldots, x_n]$ makes the polynomial ring into an A-algebra.
 - When $A \subseteq R$ the inclusion map makes R an A-algebra. In this case the A-module multiplication ar coincides with the internal (ring) multiplication on R.
 - Any ring comes with a unique structure as a Z-algebra.

The collection of A-algebras forms a category where the morphisms are ring homomorphisms $f: R \to S$ such that the following diagram commutes

for structural homomorphisms $\varphi: A \to R$ and $\psi: A \to S$.

Definition 1.3 (Algebra generation). Let R be an A-algebra and let $\Lambda \subseteq R$ be a set. The A-algebra generated by a subset Λ of R, denoted $A[\Lambda]$, is the smallest (w.r.t containment) subring of R containing Λ and $\varphi(A)$.

A set of elements $\Lambda \subseteq R$ generates R as an A-algebra if $R = A[\Lambda]$.

Note that there are two different meanings for the notation A[S] for a ring A and set S: one calls for a polynomial ring, and the other calls for a subring of something.

This can be unpackaged more concretely in a number of equivalent ways:

Lemma 1.4. The following are equivalent

- (1) Λ generates R as an A-algebra.
- (2) Every element in R admits a polynomial expression in Λ with coefficients in $\phi(A)$, i.e.

$$R = \left\{ \sum_{\text{finite}} \phi(a) \lambda_1^{i_1} \cdots \lambda_n^{i_n} \mid a \in A, \lambda_j \in \Lambda, i_j \in \mathbb{N} \right\}.$$

(3) The A-algebra homomorphism $\psi : A[X] \to R$, where A[X] is a polynomial ring on a set of indeterminates X in bijection with Λ and $\psi(x_i) = \lambda_i$, is surjective.

Proof. Let $S = \{\sum_{\text{finite}} \phi(a) \lambda_1^{i_1} \cdots \lambda_n^{i_n} \mid a \in A, \lambda_j \in \Lambda, i_j \in \mathbb{N} \}$. For the equivalence between (2) and (3) we note that S is the image of ψ . In particular, S is a subring of R. It then follows from the definition that (1) implies (2). Conversely, any subring of R containing $\phi(A)$ and Λ certainly must contain S, so (2) implies (1).

Example 1.5. We may have also seen these brackets used in $\mathbb{Z}[\sqrt{d}]$ for some $d \in \mathbb{Z}$ to describe the ring

$${a + b\sqrt{d} \mid a, b \in \mathbb{Z}}.$$

In fact, this is a special instance of generating: the \mathbb{Z} -algebra generated by \sqrt{d} in the most natural place, the algebraic closure of \mathbb{Q} , is exactly the set above. The point is that for any power $(\sqrt{2})^n$, write n = 2q + r with $r \in \{0, 1\}$, so $(\sqrt{2})^n = 2^d(\sqrt{2})^r$. Similarly, the ring $\mathbb{Z}[\sqrt[3]{d}]$ can be written as

$$\{a+b\sqrt[3]{d}+c\sqrt[3]{d^2}\ |\ a,b,c\in\mathbb{Z}\}.$$

Note that the homomorphism ψ in part (3) need not be injective.

- If the homomorphism ψ is injective (so an isomorphism) we say that A is a *free* algebra.
- the set $\ker(\psi)$ measures how far R is from being a free A-algebra and is called the set of *relations* on Λ .

Definition 1.6 (Algebra-finite). We say that $\varphi: A \to R$ is algebra-finite, or R is a finitely generated A-algebra, if there exists a finite set of elements f_1, \ldots, f_d that generates R as an A-algebra. We write $R = A[f_1, \ldots, f_d]$ to denote this.

The term *finite-type* is also used to mean this.

Remark 1.7. Note that, by the lemma on generating sets, an A-algebra is finitely generated if and only if it is isomorphic to a quotient of a polynomial ring over A in finitely many variables. The choice of an isomorphism with a quotient of a polynomial ring is equivalent to a choice of generating set.

Lecture of January 21, 2022

Example 1.8. Let K be a field, and $B = K[x, xy, xy^2, xy^3, \dots] \subseteq C = K[x, y]$, where x and y are indeterminates. Let A be a finitely generated subalgebra of B, and write $A = K[f_1, \dots, f_d]$. Since each f_i is a (finite) polynomial expression in the monomials $\{xy^i \mid i \in \mathbb{N}\}$, it involves only finitely many of these monomials. Thus, there is an m such that $\{f_1, \dots, f_d\} \subset K[x, xy, \dots, xy^m]$, and hence $A \subseteq K[x, xy, \dots, xy^m]$.

But, every element of $K[x, xy, ..., xy^m]$ is a K-linear combination of monomials with the property that the y exponent is no more than m times the x exponent, so this ring does not contain xy^{m+1} . Thus, B is not a finitely generated K-algebra.

Optional Exercise 1.9. Let $A \xrightarrow{\phi} B \xrightarrow{\psi} C$ be ring homomorphisms (so B is an A-algebra via ϕ , C is a B-algebra via ψ , and C is an A-algebra via $\psi \circ \phi$). Then

- If $A \xrightarrow{\phi} B$ and $B \xrightarrow{\psi} C$ are algebra-finite, then $A \xrightarrow{\psi\phi} C$ is algebra-finite. (Take the union of the generating sets.)
- If $A \xrightarrow{\psi \phi} C$ is algebra-finite, then $B \xrightarrow{\psi} C$ is algebra-finite. (Use the same generating set.)
- If $A \xrightarrow{\psi \phi} C$ is algebra-finite, then $A \xrightarrow{\phi} B$ may not be algebra-finite. (Use the previous example.)

Remark 1.10. Any surjective φ is algebra-finite: the target is generated by 1. Since any homomorphism $\phi:A\to R$ can be factored as $\phi=\psi\circ\varphi$ where φ is the surjection $\varphi:A\to A/\ker(\varphi)$ and ψ is the inclusion $\psi:A/\ker(\varphi)\hookrightarrow R$, to understand algebra-finiteness, it suffices to restrict our attention to injective homomorphisms by the last bullet point of the previous exercise.

There are many basic questions about algebra generators that are surprisingly difficult. Let $R = \mathbb{C}[x_1, \ldots, x_n]$ and $f_1, \ldots, f_n \in R$. When do f_1, \ldots, f_n generate R over \mathbb{C} ? It is not too hard to show that the Jacobian determinant

$$\det \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1} & \cdots & \frac{\partial f_n}{\partial x_n} \end{bmatrix}$$

must be a nonzero constant. It is a big open question whether this is in fact a sufficient condition!

1.2. **Finitely generated modules.** We will also find it quite useful to consider a stronger finiteness property for maps.

Definition 1.11. (Module generation) Let M be an A-module and let $\Gamma \subseteq M$ be a set. The A-submodule of M generated by Γ , denoted $\sum_{\gamma \in \Gamma} A\gamma$, is the smallest (w.r.t containment) submodule of M containing Γ .

A set of elements $\Gamma \subseteq M$ generates M as an A-module if the submodule of M generated by Γ is M itself, i.e. $M = \sum_{\gamma \in \Gamma} A\gamma$.

This also has some equivalent realizations:

Lemma 1.12. The following are equivalent:

- (1) Γ generates M as an A-module.
- (2) Every element of M admits a linear combination expression in the elements of Γ with coefficients in A.
- (3) The homomorphism $\theta: A^{\oplus Y} \to M$, where $A^{\oplus Y}$ is a free A-module with basis Y in bijection with Γ via $\theta(y_i) = \gamma_i$, is surjective.

Optional Exercise 1.13. Prove the previous lemma.

Definition 1.14 (Module-finite). We say that a ring homomorphism $\varphi: A \to R$ is module-finite if R is a finitely-generated A-module, that is, there is a finite set $m_1, \ldots, m_n \in M$ so that $M = \sum_{i=1}^n Am_i$.

As with algebra-finiteness, surjective maps are always module-finite in a trivial way. The notion of module-finite is much stronger than algebra-finite, since a linear combination is a very special type of polynomial expression. To be specific:

Lemma 1.15 (Module-finite \Rightarrow algebra-finite). If $\varphi: A \to R$ is module-finite then it is algebra-finite.

The converse is not true.

Example 1.16. (1) If $K \subseteq L$ are fields, L is module-finite over K just means that L is a finite field extension of K.

- (2) The Gaussian integers $\mathbb{Z}[i]$ satisfy the well-known property (or definition, depending on your source) that any element $z \in \mathbb{Z}[i]$ admits a unique expression z = a + bi with $a, b \in \mathbb{Z}$. That is, $\mathbb{Z}[i]$ is generated as a \mathbb{Z} -module by $\{1, i\}$; moreover, they form a free module basis!
- (3) If R is a ring and x an indeterminate, $R \subseteq R[x]$ is not module-finite. Indeed, R[x] is a free R-module on the basis $\{1, x, x^2, x^3, \dots\}$. It is however algebra-finite.
- (4) Another map that is *not* module-finite is the inclusion of $K[x] \subseteq K[x, 1/x]$. Note that any element of K[x, 1/x] can be written in the form $f(x)/x^n$ for some $f(x) \in K[x]$ and $n \in \mathbb{N}$. Then, any finitely generated K[x]-submodule M of K[x, 1/x] is of the form $M = \sum_i \frac{f_i(x)}{x^{n_i}} \cdot K[x]$; taking $N = \max\{n_i \mid i\}$, we find that $M \subseteq 1/x^N \cdot K[x] \neq K[x, 1/x]$.

Optional Exercise 1.17. Let $A \xrightarrow{\phi} B \xrightarrow{\psi} C$ be ring homomorphisms. Then

- If $A \xrightarrow{\phi} B$ and $B \xrightarrow{\psi} C$ are module-finite, then $A \xrightarrow{\psi \phi} C$ is module-finite.
- If $A \xrightarrow{\psi \phi} C$ is module-finite, then $B \xrightarrow{\psi} C$ is module-finite.

We will see that $A \xrightarrow{\psi \phi} C$ is module-finite does not imply $A \xrightarrow{\phi} B$ is module-finite soon.

1.3. **Integral extensions.** In field theory, there is a close relationship between (vector space-)finite field extensions and algebraic equations. The situation for rings is similar.

Definition 1.18 (Integral element/extension). Let $\phi: A \to R$ be a ring homomorphism (for which we will denote $\phi(a)$ by a) and $r \in R$. The element r is *integral* if there are elements $a_0, \ldots, a_{n-1} \in A$ such that

$$r^{n} + a_{n-1}r^{n-1} + \cdots + a_{1}r + a_{0} = 0$$
:

i.e., r satisfies a equation of integral dependence over A. The homomorphism ϕ is integral if every element of R is integral over A.

Example 1.19. Let $A = \mathbb{Z}[\sqrt{2}] = \{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$. The element $t = \sqrt{2} \in A$ is integral over \mathbb{Z} , since $t^2 - 2 = 0$. Likewise, $s = 1 + \sqrt{2}$ is integral over \mathbb{Z} , as $s^2 = 3 + 2\sqrt{2}$, so $s^2 - 2s - 1 = 0$.

On the other hand, $\frac{1}{2} \in \mathbb{Q}$ is not integral over $\mathbb{Z} \colon$ if

$$\left(\frac{1}{2}\right)^n + a_{n-1} \left(\frac{1}{2}\right)^{n-1} + \dots + a_0 = 0$$

with $a_i \in \mathbb{Z}$, multiply through by 2^n to get $1 + 2a_{n-1} + 2^2a_{n-2} + \cdots + 2^na_0 = 0$, which is impossible.

Lecture of January 24, 2022

Proposition 1.20. Let $A \subseteq R$ be rings.

- (1) If $r \in R$ is integral over A then A[r] is module-finite over A.
- (2) If $r_1, \ldots, r_t \in R$ are integral over A then $A[r_1, \ldots, r_t]$ is module-finite over A.
- Proof. (1) Suppose r is integral over A, satisfying the equation $r^n + a_{n-1}r^{n-1} + \cdots + a_1r + a_0 = 0$. Then $A[r] = \sum_{i=0}^{n-1} Ar^i$. Indeed, $s \in A[r]$ with a polynomial expression $s = p(r) = \sum c_j r^j$ of degree $m \ge n$, we can use the equation above to rewrite the leading term $a^m r^m$ as $-a_m r^{m-n} (a_{n-1} r^{n-1} + \cdots + a_1 r + a_0)$, and decrease the degree in r.

(2) Write $A_0 := A \subseteq A_1 := A[r_1] \subseteq A_2 := A[r_1, r_2] \subseteq \cdots \subseteq A_t := A[r_1, \ldots, r_t]$. Note that r_i is integral over A_{i-1} : use the same monic equation of r_i over A. Then, the inclusion $A \subseteq A[r_1, \ldots, r_t]$ is a composition of module-finite maps, hence is module-finite.

We recall that the *classical adjoint* of an $n \times n$ matrix A is the $n \times n$ matrix whose (i, j)-entry is $(-1)^{i+j}$ times the determinant of the matrix obtained from A by removing the ith column and the jth row.

Lemma 1.21 (Determinantal trick). Let R be a ring, $B \in M_{n \times n}(R)$, $v \in R^{\oplus n}$, and $r \in R$.

- (1) $\operatorname{adj}(B)B = \det(B)I_{n \times n}$.
- (2) If Bv = rv, then $det(rI_{n \times n} B)v = 0$.
- *Proof.* (1) When R is a field, this is a basic linear algebra fact. We deduce the case of a general ring from the field case.

The ring R is a \mathbb{Z} -algebra, so we can write R as a quotient of some polynomial ring $\mathbb{Z}[X]$. Let $\psi : \mathbb{Z}[X] \longrightarrow R$ be a surjection, $a_{ij} \in \mathbb{Z}[X]$ be such that $\psi(a_{ij}) = b_{ij}$, and let $A = [a_{ij}]$. Note that

$$\psi(\operatorname{adj}(A)_{ij}) = \operatorname{adj}(B)_{ij}$$
 and $\psi((\operatorname{adj}(A)A)_{ij}) = (\operatorname{adj}(B)B)_{ij}$,

since ψ is a homomorphism, and the entries are the same polynomial functions of the entries of the matrices A and B, respectively. Thus, it suffices to establish

$$\operatorname{adj}(B)B = \det(B)I_{n \times n}$$

in the case when $R = \mathbb{Z}[X]$, and we can do this entry by entry. Now, $R = \mathbb{Z}[X]$ is an integral domain, hence a subring of a field (its fraction field). Since both sides of the equation

$$(\operatorname{adj}(B)B)_{ij} = (\det(B)I_{n \times n})_{ij}$$

live in R and are equal in the fraction field (by linear algebra) they are equal in R. This holds for all i, j, and thus 1) holds.

(2) We have $(rI_{n\times n} - B)v = 0$, so by part 1)

$$\det(rI_{n\times n} - B)v = \operatorname{adj}(rI_{n\times n} - B)(rI_{n\times n} - B)v = 0. \quad \Box$$

Theorem 1.22. Let $A \subseteq R$ be module-finite. Then R is integral over A.

Proof. Given $r \in R$, we want to show that r is integral over A. The idea is to show that multiplication by r, realized as a linear transformation over A, satisfies the characteristic polynomial of that linear transformation.

Write $R = Ar_1 + \cdots + Ar_t$. We may assume that $r_1 = 1$, perhaps by adding module generators. By assumption, we can find $a_{ij} \in A$ such that

$$rr_i = \sum_{j=1}^t a_{ij} r_j$$

for each i. Let $C = [a_{ij}]$, and v be the column vector (r_1, \ldots, r_t) . We have rv = Cv, so by the determinant trick, $\det(rI_{n\times n} - C)v = 0$. Since we chose one of the entries of v to be 1, we have in particular that $\det(rI_{n\times n} - C) = 0$. Expanding this determinant as a polynomial in r, this is a monic equation with coefficients in A.

Collecting the previous results, we now have a useful characterization of module-finite extensions:

Corollary 1.23 (Characterization of module-finite extensions). Let $A \subseteq R$ be rings. R is module-finite over A if and only if R is integral and algebra-finite over A.

Proof. (\Rightarrow): A generating set for R as an A-module serves as a generating set as an A-algebra. The remainder of this direction comes from the previous theorem. (\Leftarrow): If $R = A[r_1, \ldots, r_t]$ is integral over A, so that each r_i is integral over A, then R is module-finite over A by Proposition 1.20.

Corollary 1.24. If R is generated over A by integral elements, then R is integral. Thus, if $A \subseteq S$, the set of elements of S that are integral over A form a subring of S.

Proof. Let $R = A[\Lambda]$, with λ integral over A for all $\lambda \in \Lambda$. Given $r \in R$, there is a finite subset $L \subseteq \Lambda$ such that $r \in A[L]$. By the theorem, A[L] is module-finite over A, and $r \in A[L]$ is integral over A.

For the latter statement, the first statement implies that

 $\{\text{integral elements}\}\subseteq A[\{\text{integral elements}\}]\subseteq \{\text{integral elements}\},$

so equality holds throughout, and {integral elements} is a ring.

Example 1.25. (1) Not all integral extensions are module-finite. Let $K = \overline{K}$, and consider the ring

$$R = K[x, x^{1/2}, x^{1/3}, x^{1/4}, x^{1/5}, \dots] \subseteq \overline{K(x)}.$$

Clearly R is generated by integral elements over K[x], hence integral, but is not algebra-finite over K[x].

(2) Let x, y, z be indeterminates. Set $R = \mathbb{C}[x, y]$ to be a polynomial ring, and $S = \mathbb{C}[x, y, z]/(x^2 + y^2 + z^2)$ to be a quotient of a polynomial ring. We claim that we can realize R as a subring of S; i.e., the \mathbb{C} -algebra homomorphism from R to S that sends x to x and y to y is injective. Indeed, the kernel is the set of polynomials in x, y that are multiples of $z^2 + x^2 + y^2$, but, thinking of $\mathbb{C}[x, y, z]$ as R[z], any nonzero multiple of $z^2 + x^2 + y^2$ must have z-degree at least 2, so none only involve x, y. Thus, we have an inclusion $R \subseteq S$.

The ring S is module-finite over R: indeed, S is generated over R as an algebra by one element z that is integral over R.
